## INTRODUCTION

This report summarizes and analyzes data on community sewage works in the United States based on the 1957 Inventory of Municipal and Industrial Wastes Facilities (1). This is the third such study prepared by the Public Health Service (2), (3).

Comprehensive data are presented by States, major drainage basins, and community size groups.

### History

The Public Health Service initiated comprehensive activities in the compilation of water and sewage statistics in 1939. Such data have been gathered since that time in varying forms. (For a more complete discussion of Inventory development see Supplement 213—Public Health Reports (3).)

Following passage of the Water Pollution Control Act of 1948 (P. L. 845, 80th Congress), the items collected concerning sewage works were expanded, and data on industrial wastes sources were added. These data were listed by drainage basins and, when analyzed, furnished base information for the development of comprehensive programs for the control of water pollution. At the same time that these data were being assembled, the Public Health Service was continuing the compilation of its Inventory of Water and Sewage Facilities in cooperation with the state health departments. Since both sewage works listings were similar, it was logical that they be combined.

Separate listings were developed; one for water supply facilities, the other for sewage and industrial wastes facilities. The data items included in the latter listing are shown in the form headings reproduced in Figure 1.

Beginning in 1952, these data were requested from the State agency responsible for water pollution control activities. While many States have produced annual revisions of the inventory beginning in 1953, the listings for the entire United States were not available until 1957.

A National Inventory of Sewage and Industrial Wastes Facilities is currently being prepared for printing, and will be available for distribution in the fall of 1958.

Reports as received from the various State agencies were edited and then embossed on metal address plates. Using normal listing equipment which extends lines of data listed vertically on the plates to a horizontal position on the forms, the inventories were printed. While plates are

filed alphabetically within a State, the use of small metal tabs for coding permits the preparation of listings by drainage basins, State administrative regions, or other breakdowns depending on requirements. Corrections of reports are handled by reembossing only the items affected or by complete reembossing depending on the number of corrections.

## I. BASIC DATA

### Methods

This summary is based on the data contained in the 1957 Inventory of Sewage and Industrial Wastes Facilities; however, 1953 data were the latest available for Alabama, Michigan, and Louisiana. In preparing this summary report only those entries pertaining to municipal sewage facilities were used. All institutional and industry data were eliminated from consideration. The term "municipal" includes not only incorporated and unincorporated communities, but also sanitary districts in their many forms, and such places as mill villages where there is a permanent resident population engaged in the normal domestic pattern of living.

The basic Inventory listings were checked for omissions and irrelevancies, certain data were interpreted for coding, and all pertinent items were punched into cards. Programs were developed and the tabular material produced using modern, high-speed machine tabulating equipment. While this processing method proved superior to older, hand-tabulation procedures, the time necessary for processing due to the wide data spread and the machines' physical limitations indicated the need for programming future summaries using electronic computers.

The basic tabular data are shown in three major classifications: population groups, States, and drainage basins. In one instance, data are grouped by the standard Census Bureau geographical areas.

Figure 1—Continued.

Ranges for the population groups used are as follows:

Group	Population Range
1.....	Under 500
2.....	500-1,000
3.....	1,000-5,000
4.....	5,000-10,000
5.....	10,000-25,000
6.....	25,000-50,000
7.....	50,000-100,000
8.....	100,000 and over

Individual entries were assigned to a particular population group on the basis of the 1950 census population of the community. For those unincorporated places where census data were not available, and where the State water pollution control agency had not furnished a "census" population, data from the 1956 Rand-McNally Commercial Atlas were used. Lacking this, the estimated population served was used as the "census" population. Sanitary and other special districts were classified in the group represented by the estimated population served where no "census" population was attributable to the entry.

The United States was divided into drainage basins by the Public Health Service following passage of the Water Pollution Control Act of 1948. With but minor modification, these same basins have been used for this report. The following is the list of the major basins:

Northeast  
North Atlantic  
Southeast  
Tennessee River  
Ohio River  
Lake Erie  
Upper Mississippi  
Western Great Lakes

Missouri River  
Southwest—Lower Mississippi  
Colorado River  
Western Gulf  
Pacific Northwest  
California  
Great Basin

Figure 2 delineates these basins on a United States map.

These basins are further broken down into 242 subbasins. Data have been tabulated by these subbasins, but are not reproduced in this report. This detailed information has been furnished to the cooperating organizations, and is on file at the Washington headquarters of the Public Health Service's Water Supply and Water Pollution Control Program.

## MAJOR RIVER BASINS OF THE UNITED STATES

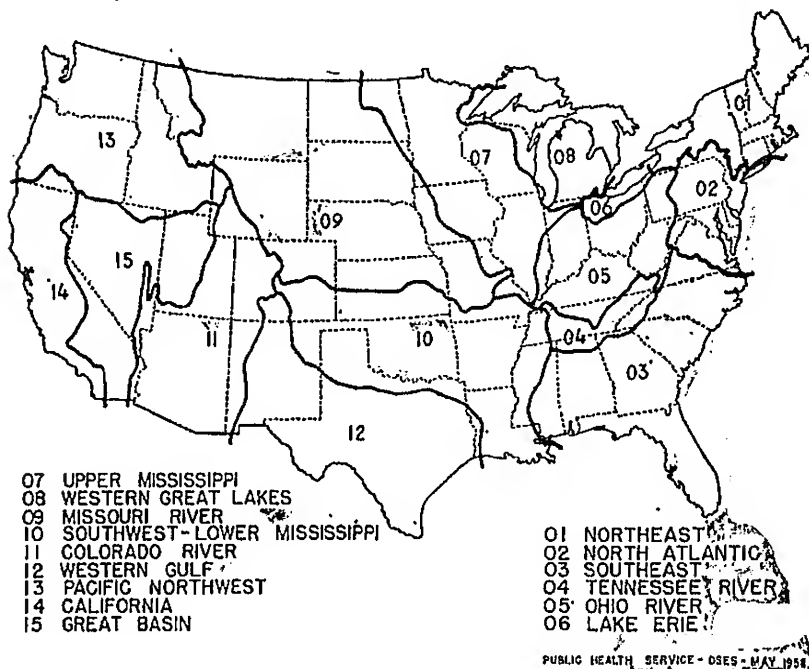

Figure 2.

Data for estimated population served were quite complete in the inventory listing. Where such data were not available, the census populations, rounded to the nearest 10, were used. These cases comprise the only instances where arbitrary procedures were used to add individual data items to the inventory. All other data items are as furnished by the reporting agency.

In the summary data none of the estimated population-served figures has been rounded off, because of inherent difficulties in adjusting several sets of comparable data simultaneously. No fictitious precision is imputed to these data, however, since they are, at best, only estimates.

## Summary Data

The basic data produced in this summary are presented in nine tables. National summaries are given in tables 1, 2, and 3 for sewer systems,

sewage disposal and treatment. Detailed data by States, population groups, and major drainage basins are presented in tables 5 through 9, inclusive.

The data in tables 1, 2, and 3 represent a portion of the data appearing in the total columns of the detailed tables. They are presented as separate items for clarity and comparison, and for a quick summary of nationwide conditions.

Both tables 2 and 3 present additive data, as do the corresponding detailed tables (6 and 7). Where more than one type of settling tank was present in a primary plant, the plant was classified in an "other" category. In secondary treatment plants, two or more secondary processes are often present. Rather than present only unit process data which are not additive, secondary plants were arbitrarily assigned to a process on the following basis for table 7. Land application, oxidation ponds, and sand filters were considered subsidiary to either activated sludge or trickling filter processes. As a consequence, where any of these processes followed an activated sludge process or a trickling filter, they were not counted in this table. Both land application and oxidation ponds were considered subsidiary to sand filters. In a very few instances, both trickling filters and the activated sludge process appeared in the same plant. These cases were individually examined and assigned on the basis of professional judgment.

Table 1. *General and treatment summary for the United States*

	Number	Percent
Number of communities		
—with sewer systems	11, 131	.....
—discharging raw sewage only	3, 065	27.5

Total.....	98,361,396	98,361,396	20,140,570	20,140,578

<sup>1</sup>"Sewage Disposal"—The act of disposing of sewage by any method. The term is not synonymous with "Sewage Treatment." Glossary Water and Sewage Control Engineering, American Society of Civil Engineers, 1949.

Data for certain selected processes used in intermediate and secondary treatment plants are presented in table 8. These data are not additive, and both plants and populations have been counted under multiple headings where two or more processes are present in the same plant.

The data reported in table 9 for sludge processing are not additive. Where several processes occurred in one plant, the plant was counted under the various headings. Since it is not possible to distribute the population served among the various processes used in a single plant, such data are not included.

Table 4 presents population served data by the various population groupings, in order to relate them properly to the census population of the communities within each population group. Normal data processing techniques count communities and census populations within the proper group. However, if the sewage is disposed of through another community or a sanitary district, the population served is counted for the group in which the other community or sanitary district falls. Without special treatment of the data, comparisons are not adequate. Column 3 of this table shows the population connected to sewers within the communities of the particular group, while column 2 shows the population which is served by disposal facilities of communities in that group or by special districts classified in that group. Columns 4 and 5 show the population interchange when sewage is disposed of through nonlocal facilities.

Table 5. *Summary of sewer systems and sewage disposal by population groups, States and drainage basins*

## II. ANALYSIS AND INTERPRETATION

### General

In 1957, 11,131 communities in the United States had sewer systems serving 98.4 million persons. This was slightly more than 57 percent of the total estimated population of the country in that year. These sewer systems served communities having a census population of 102 million, of whom 96.4 percent were connected to the sewer systems.

Of the 98.4 million population seweraged, 22.3 percent discharged raw sewage and 77.7 percent treated sewage. If minor treatment—less than sedimentation—is not considered as treatment, sewage from 75.8 percent of the population connected to sewers is treated.

The 76.4 million persons served by treatment resided in 8,066 separate communities and were served by 7,518 treatment plants. The majority, 61.8 percent, of these plants furnished secondary treatment, and served 56.7 percent of the population served by treatment. Secondary treatment plants served 44 percent of the total population connected to sewers.

#### *States*

The percent of census population in seweraged communities connected to the sewer systems varied considerably among the States, ranging from 74.5 percent in New Hampshire to over 140 percent in Nevada. The percentages by States for this item are given in table 10, together with percentages of connected population from which sewage is discharged raw or treated for both 1945 and 1957. The percent of census population seweraged exceeds 100 percent in some cases because 1957 estimated population served data are compared to 1950 census population data.

In 16 States the population served by treatment exceeds 90 percent of the total seweraged population. This is twice as many States as reported such a high percentage in 1945. As noted above, treatment is provided for 77.7 percent of the population served by sewers. This nationwide figure is exceeded in 23 States. In 1945 the population served by treatment was less than 20 percent of the seweraged population in 9 States, while in 1957 this had been reduced to 2 States, Maine and New Hampshire.

#### *Geographical Areas*

Census Bureau geographical area groupings have been used in table 11 for the purpose of analyzing general sewage works data. The States included in each group are listed in the footnotes of this table. The grouping of data on a geographic basis such as is used here is not entirely pertinent to evaluation of sewage works. However, the groups are

standard ones used for a variety of governmental statistics, and their use here permits comparisons to be made with data in other fields that might be pertinent to an analysis of a special problem. In addition, the States in each group afford some homogeneity of economic, industrial, and social patterns.

Table 10. *Percent of census population in sewerred communities connected to sewers and raw and treated discharge—by States*

State	Population connected in sewerred communities, percent of census population	Percent of connected population sewage discharged

Wisconsin.....	97.2	8.7	3.9	91.3	96.1
Wyoming.....	104.1	63.9	56.0	36.1	64.0
Total.....	96.4	37.3	22.3	62.7	77.7

<sup>1</sup> These percentages are not shown, since they are unrealistic due to the effect of the Washington Suburban Sanitary Commission discharging to the District of Columbia plant.

On this basis the variations in percentage data are materially reduced. Only in the Pacific area does the percent of sewered population connected to treatment facilities exceed 90 percent. The corresponding low percentage is for the East South Central group where 55.7 percent is served by treatment. This latter figure compares with only 31.3 percent treated in 1945 in the same group of States, indicating substantial progress.

Table 11. *Population served by sewers and sewage treatment—by geographical areas*

### Drainage Basins

Analytical data for the major drainage basins used in this report are presented in table 12. The North Atlantic basin has 10.9 percent of the total sewered communities in the United States, but these contain 22.0 percent of the population. The Upper Mississippi basin has the largest percentage of communities, 13.9 percent. In the Western Gulf basin sewage from almost 98 percent of the sewered population is treated while in the Great Basin only 49.8 percent of the population is so served.

While the above data types are interesting in developing a national picture of pollution conditions, the administrative arrangements necessary to solve the remaining raw sewage discharge problem are pointed out in the community analysis portion of table 12. In the Ohio River Basin over 58 percent of the population is served by treatment—lower than the national average of 77.7 percent, but a reasonable figure when considered in light of what existed in this basin 10 to 12 years ago. Yet, 52 percent of the communities in the Ohio basin discharge all of their sewage raw. The administrative complexities of dealing with this substantial percentage of communities in the solution of their sewage problems are obviously greater in proportion than in some other drainage

areas. While enforcement of and compliance with pollution-control measures is along State lines, the development of the basin concept over the last 20 years makes comparisons of this type necessary for proper evaluation of program operations.

Table 12. *Percentage data for sewer systems and raw and treated discharge—by drainage basins*

### Population Groups

Table 13 presents data showing the percentage distribution among the various groups for sewerred communities, census population of these communities, connected population, populations discharging raw and treated sewage, and number of treatment plants.

Disposal facilities of communities in group 8 or of sanitary districts classed in this group serve 53.2 percent of the total United States sewerred population, approximately the same percentage as in 1945. However, this same group accounts for only 1.0 percent of the sewerred communities in the United States, and for 2.2 percent of the total treatment plants.

In general, the percentage data developed in this table closely parallel similar data for 1945. The major difference is in the percent of total sewerred communities for those of less than 500 population. This increased to 11.3 percent in 1957 from 8.8 percent in 1945.

The percent of census population connected to sewers within each group, together with the percent of population discharging raw and treated sewage for both 1945 and 1957, is given in table 14.

For 1957, there are no discernible patterns for percent of census population served by sewers, whereas, in 1945, there were increasing percentages with increasing community size except for group 1.

In 1945, three of the groups bettered the national percentage of treated discharge, while in 1957 only group 8 exceeds the national average. However, all groups have experienced substantial increases in the percent of sewered population served by treatment plants. The largest such increase was in group 7, where the percentage increased from 54.3 in 1945 to 74.6 percent in 1957.

Table 13. *Percentage data for sewer systems and raw and treated discharge—by population groups*

Population size groups	Percent of total number of sewered communities	Percent of 1950 census population of sewered communities	Percent of total population connected				Percent of total number of treatment plants

<sup>1</sup> 0.2 percent discharging through semipublic facilities not included.

<sup>2</sup> 0.1 percent discharging through semipublic facilities not included.

### Comparison with Prior Data

Selected comparative data from earlier statistical summaries are presented in table 15. The 1957 Inventory shows an increase of 2,214 community sewer systems and almost 24 million persons served over the 1945 data. These represent increases of 24.8 and 31.6 percent, respectively. The increase in population served by treatment facilities was 63.1 percent during this same period, while there was a decrease of 21.4 percent in the number of persons connected to raw sewage discharges.

Table 15. Comparative data for 1940-57 for sewage disposal systems

	1940	1945	1948	1949	1957
Number of sewered communities . . .	8,516	8,917	{ <sup>a</sup> }	{ <sup>a</sup> }	11,131
Census population . . . . .	175,729,000	182,012,692	76,680,685	78,850,870	2102,047,712
Estimated population connected . . .	70,506,000	74,740,807			93,361,396
Percent of census population connected . . . . .	93.1	91.1			96.4
Raw discharge:					
Number of communities . . . . .	3,597	3,610	3,800	3,718	3,165
Estimated population served . . . . .	29,089,000	27,867,783	27,982,490	28,067,350	21,917,665
Percent of total sewered population . . . . .	42.4	37.3	36.5	35.6	22.3
Treated discharge:					
Number of Communities . . . . .	5,085	5,400	{ <sup>a</sup> }	{ <sup>a</sup> }	8,066
Estimated population served . . . . .	40,617,000	46,865,114	40,698,195	50,783,520	76,443,731
Percent of total sewered population . . . . .	57.6	62.7	63.5	64.4	77.7

<sup>a</sup> Data not available.

<sup>1</sup> 1940 census data.

<sup>2</sup> 1950 census data.

<sup>3</sup> Includes 166 communities discharging both raw and treated sewage.

<sup>4</sup> Includes 173 communities discharging both raw and treated sewage.

<sup>5</sup> Includes communities where only part of sewage is discharged untreated.

<sup>6</sup> Includes 100 communities discharging both raw and treated sewage.

<sup>7</sup> Includes 7,990 population discharging through semi-public facilities and not included in discharge data.

Since 1940 the percentage of total sewered population connected to raw discharge facilities has declined almost one-half. While this indicates substantial progress, the decline in total population in this category for 1940-1957 has only been 26.7 percent. The obvious conclusion is that treatment has been keeping abreast of population increases, but that it has not made substantial reductions in the population discharging raw sewage during the last 17 years. Tentative estimates based on these data indicate there has even been a small increase in population equivalents from community systems discharged to the streams of the Nation.

Table 16 presents data for 1940, 1945, and 1957 relating to population served and population discharged to the stream based on assigned percentage reductions for the various degrees of treatment. These reductions were derived from population equivalent data reported in the 1957 Inventory for approximately 56 percent of the sewered population. Table 16 is based on "population" only, since comparable population equivalent data are not available for years earlier than 1957.

Table 16. Sewage discharge to watercourses in 1940, 1945, and 1957

Treatment	Assigned percent reduction	Estimated population discharged—1000's		
		1940	1945	1957
None . . . . .	0.0	29,889	27,868	21,918
Minor . . . . .	0	3,288	4,270	1,860
Primary . . . . .	31.3	10,896	11,798	17,633
Intermediate . . . . .	45.5	2,201	2,051	3,047
Secondary . . . . .	82.5	3,178	3,790	7,582
Total . . . . .		48,952	49,777	52,040

This analysis indicates that an increase of 4.5 percent in the total population discharged to streams occurred in the period 1945-1957, and that an increase of 6.3 percent occurred during the 1940-1957 period.

Even with the remarkable increases in population served by sewage treatment since 1945, the fact that sewage from over 52,000,000 persons is still discharged to the Nation's streams is cause for reflection as to the efficacy of current pollution-abatement programs.

Preliminary population equivalent data extrapolated for the entire sewered population indicate that community sewer systems receive in excess of 140 million population equivalents. These same preliminary adjustments further indicate that approximately 75 million population equivalents are discharged to streams. This entire group of data is being subject to special study which will be reported in a later paper.

### *Development of Community Sewer Systems*

During the years since World War II, there has been a marked increase in the urban population with the concomitant development of the so-called metropolitan area. Data presented by Hyde (4) indicate that in the urban population a lag of 5 to 8 million persons not served by community sewer systems has existed since 1860. In 1945 (3) the lag was approximately 7 million persons. The data in this summary indicate a lag of only 3.7 million persons. While the census population used for comparison is mainly for 1950, the application of a ratio of 1957 to 1950 census data for the entire United States would increase the lagged population to only slightly over 4 million persons. In addition, the percent of total United States population sewered in 1957 increased to 57.5 percent from approximately 53 percent for 1940 through 1949. Table 17 presents information showing the development of community facilities.

These two facts tend to indicate that the new urban population is being connected to sewer systems as it develops, and that some headway has been made in reducing the population resident in urban areas but not served by the community sewer systems.

Over 2,200 communities have installed sewer systems since 1945, an increase in number of almost 25 percent. The corresponding increase in sewered population is almost 32 percent. The increase from 1945 to 1957 in the census population of sewered communities is slightly less than 25 percent. Since the sewered population increase is substantially greater than the corresponding increase in census population of sewered communities, further credence is given to the statement that there is a trend toward reduction of the population in urban communities not connected to sewer systems.

As would be surmised, the preponderance of sewered communities is in the smaller population size groups. Almost 76 percent of sewered communities had less than 5,000 population, and 95.1 percent had less than 25,000. Contrasted to this, the large populations served are in the larger population size groups. The communities of over 100,000 popu-

lation comprise only 1.0 percent of the total communities yet they furnish 44.7 percent of the population connected to sewers, and serve over 53 percent of this population through their raw discharge or treatment facilities. These percentages are slightly less than those in 1945. These data are shown in table 13, and accumulated percent data for 1945 and 1957 are shown in table 18.

Table 17. *Development of sewer systems in the United States*

Year	Total United States population—millions	Sewage facility development	
		Numbered of sewer communities	Population served by sewers—millions
1860 <sup>1</sup> .....	31.4	10	1.0
1870.....	38.6	100	4.5

Table 18. *Percent of total sewer communities and connected population by population groups*

Population size groups	Communities sewerd (accumulated percent of total)		Estimated connected population (accumulated percent of total)	
	1945	1957	1945	1957
Under 500.....	8.8	11.3	0.3	0.4
500-1,000.....	27.6	28.9	1.6	1.7
1,000-5,000.....	76.3	75.7	11.9	12.6
5,000-10,000.....	87.6	87.1	19.7	21.2
10,000-25,000.....	95.3	95.1	31.9	35.1
25,000-50,000.....	97.7	97.8	41.6	45.6
50,000-100,000.....	98.9	99.0	51.2	55.3
Over 100,000.....	100.0	100.0	100.0	100.0

The data in table 18 present some interesting items. Other than in the smallest two groups the accumulated percentages of total number of sewer communities were practically the same in 1957 as in 1945, while some rather significant divergences are apparent in the accumulated percentages of estimated populations connected to sewer systems. While the increase in number of sewer communities appears to have been distributed among the several groups proportionate to conditions existing

in 1945, the connected population increase has been proportionately larger in the communities between 5,000 and 50,000.

In the 1945 summary (3) it was pointed out that while the largest community group (over 100,000 population) was the dominant one with respect to population served, the practice in the communities of this group was, in almost every case, a special problem, and, that this does not represent sewage works practice in the United States. This statement is just as pertinent when the 1957 data are considered, and may be even more so when some of the above facts are considered.

### *Sanitary Districts and Communities Serving Others*

As reported in the 1957 Inventory, over 20.1 million persons in the United States were served by raw discharge or treatment facilities of other communities or sanitary districts. This is a 65-percent increase over similar data in 1945. With respect to special districts which discharge sewage from the majority of the population included in the 20.1 million figure, it should be noted that only those districts are included which were reported as such by the States as separate inventory listings. There are undoubtedly other such districts, many of whose boundaries are conterminous with the community they serve, whose existence as such has not been reported, and hence are not reported in this summary.

While some of the increase in population served by other communities and/or special districts may be ascribed to better reporting, the conclusion is obvious that this method of sewage disposal is being resorted to much more frequently. In table 19 the percentage interchange of population among communities for 1945 and 1957 are shown. There has been a substantial increase in population served by other communities or sanitary districts for the communities in the smaller groups, and a concomitant rise in the population received by facilities of the largest group for disposal. It may well be argued that this is a gratifying development, since larger plants are normally better operated and designed more rationally. However, the situation still remains that most of the smaller communities are so situated that they cannot avail themselves of such favorable circumstances as connection to larger systems. Their problems are no less real, however, and invite the concern of official agencies.

### *Type of Sewers*

Data from over 10,500 communities reported in the inventory indicate that 82.1 percent are served by separate sewer systems, 13.8 percent by combined sewer systems, and the remainder have both separate and combined sewers. Table 20 shows the percentage of each type sewers within each population group. During the period 1945 to 1957 there was an actual decrease in the number of communities reporting combined sewer systems, with practically all of the increase being reported for communities having separate sewers. It appears that the trend is toward separate systems, exclusively.

Table 19. *Percent of sewered population served by or serving others—by population groups*

	Year	Population size groups

## TREATMENT

More than 76 million persons in the United States were served by 7,518 treatment plants in 1957. Table 1 shows the number of plants and population served for each degree of treatment, together with corresponding percentages.

Secondary treatment serves the largest number of persons and accounts for almost 57 percent of all plants. Since 1945 there has been a 100-percent increase in the number of persons served by secondary treatment and a two-thirds increase in the number of secondary plants. These percentage-change data, together with other available comparative data for the years 1940 to 1957, are shown in table 21.

Significantly, there have been decreases since 1949 in the numbers of plants for all degrees of treatment other than secondary, and substantial decreases in the number of persons served by treatment of less than sedimentation for both the 1949-1957 and 1945-1957 periods.

The percentage distributions within population groups and drainage basins for number of plants and population served for the various degrees of treatment are presented in tables 22 and 23, respectively.

With respect to population groups, and with the exception of intermediate treatment, no significant patterns are discernible. Intermediate

treatment frequency increases as does the size of community as to both numbers of plants and populations served.

On the other hand, there are quite significant differences in practice among the drainage basins. In the Western Gulf basin almost 97 percent of the population connected to treatment is served by secondary plants, compared with less than 23 percent so served in the Northeast basin. The Missouri River basin has the highest percentage of population served by intermediate treatment, while the Pacific Northwest basin reports the greatest percentage served by primary treatment. There appears to be some correlation between the degree of treatment and the degree of industrialization with possible correlation, also, with population density or degree of urbanization. Such an analysis, however, has not been made for this report, and any definite conclusions await further study.

Table 21. *Sewage treatment data—1940 to 1957*

NUMBER OF PLANTS							
Degree of treatment	1940	1945	1948	1949	1957	Percent change <sup>3</sup>	
						1945-57	1949-57

<sup>1</sup> Includes 12 plants—unknown treatment.

<sup>2</sup> Includes 25,000—unknown treatment.

<sup>3</sup> ( ) denotes decrease.

### *Primary Treatment*

In 1957 there were 2,730 primary treatment plants in the United States serving almost 26 million persons. Table 2 shows the number of plants and estimated population served for the several types of plants, together with corresponding percentages.

Imhoff tank plants are the most numerous type, comprising almost 40 percent of all primary plants. In 1945, Imhoff tank and septic tank plants together comprised 83.5 percent of the total primary plants, and served 36.0 percent of the population. In 1957 these percentages had declined to 68.3 and 16.8 percent, respectively. While the number of Imhoff plants increased from 1945 to 1957, there was a 31.2 percent decrease in the population served. The corresponding decrease for septic tank plants was 25.5 percent.

Table 22. Number of plants and population served by degree of treatment—percent of total within each population size group

					36.3	33.6	1.3	7.3	61.3	56.7

The increase in mechanically cleaned tank primary plants was substantial. They comprise almost one-fourth of all primary plants, but serve 72.7 percent of the overall population. From 1945 to 1957 they increased over 84 percent in numbers and 95.1 percent in population served.

Table 24 shows the percent of plants of various types as well as connected population within each population group. Table 25 reports the same data by drainage basins. In general, septic tank and Imhoff plants predominate in the smaller groups, with mechanically cleaned tank plants coming into major use in the communities of over 5,000 population. Considerable variation in practice exists among the various basins. In the Pacific Northwest basin over 93 percent of the population served by primary treatment is connected to plants with mechanically cleaned tanks. The corresponding figure is only 4.4 percent in the Western Gulf basin.

### *Intermediate and Secondary Treatment*

Almost 49 million persons in the United States are served by 4,747 intermediate and secondary treatment plants. The activated sludge process is used in 589 plants serving 24.8 million persons—over 57 percent of the total population served by secondary treatment. Trickling filters, both standard and high rate, total 2,682 plants and serve over 15 million persons. Intermediate treatment is defined as chemical treatment with sedimentation in the absence of any secondary process. There are 100 such plants serving 5.6 million persons.

Percentage distribution within population groups and drainage basins for the various major secondary treatment processes are shown in tables 26 and 27. Activated sludge plants are the predominant type in cities of over 25,000 population. Standard rate trickling filters predominate in the communities under this size. The use of oxidation ponds is a major item in group 1—less than 500 population.

The distribution of plant types by drainage basins shows considerable variation in practice. In the Lake Erie basin, almost 55 percent of the plants are of the activated sludge type while in the Colorado River basin only 5.2 percent are reported. In this latter basin, 43.7 percent of the plants are oxidation ponds. Sand filters continue to be a major plant type only in the Northeast basin. High-rate trickling filters comprise a majority of 52.7 percent of the plants in the Pacific Northwest basin.

As explained in the introductory section, two types of data are presented concerning intermediate and secondary treatment. First is additive data where plants incorporating two or more processes have been arbitrarily assigned to a type of plant. In former summaries (2), (3) data were arranged on a unit process basis. This type of arrangement has been continued to present comparable data.

Comparative data are presented in table 28 for the years 1940, 1945, and 1957. The population served by the activated sludge process

Table 29. *Plants providing chlorination and grit removal by population groups*

Population size groups	Percent of total plants providing—			
	Chlorination		Grit removal	
	1945	1957	1945	1957
Under 500.....	15.1	18.1	2.3	1.9
500-1,000.....	15.4	18.6	3.9	6.6
1,000-5,000.....	19.7	26.6	9.5	16.0
5,000-10,000.....	29.8	39.4	22.9	36.4
10,000-25,000.....	36.5	49.1	32.5	49.7
25,000-50,000.....	33.3	63.8	36.9	66.8
50,000-100,000.....	32.4	54.5	52.1	76.8
Over 100,000.....	37.7	54.9	52.5	72.0
Total.....	21.8	29.5	13.2	21.0

increased from 11.6 to 25.0 million during the 1945-57 period. This represents the largest increase. The greatest percentage increase during this period was for oxidation ponds. The number of plants increased from 45 to 631, and the population served increased from 0.2 to 2.4 million.

### *Sludge Digestion*

Units for the digestion of sewage sludge were classified under four headings: Septic tanks, Imhoff tanks, separate, and stage. Separate sludge digestion units increased over 100 percent from 1945, to a total of 2,790 plants. Imhoff tanks were used for sludge digestion in 2,759 plants. Separate digestion units comprised a majority of digestion facilities in plants located in communities of over 5,000 population. Imhoff tanks and septic tanks predominate in the smaller plants.

### *Sludge Dewatering*

Sludge drying beds are reported in use at 5,342 plants—71.1 percent of all treatment plants. Over 1,700 plants are listed as not having sludge dewatering or other organized method of drying in use. The majority of these plants are small septic tank or Imhoff tank plants, where sludge is drawn infrequently. It is probable that some of the plants reported in

this category may have drying units that have not been reported in the inventory.

### *Chlorination*

Almost 38 million persons are served by 2,216 plants incorporating chlorination facilities. This comprises 49.5 percent of the people served by treatment and 29.5 percent of the treatment plants. In 1945, comparable percentages were 34.2 and 21.8, respectively. The increase in population served since 1945 is 136.0 percent and in the number of plants is 75.6 percent.

As in 1945, New York and New Jersey have the largest number of plants equipped for chlorination—183 and 176 respectively. California and New York have the largest populations served by chlorination.

The provision of chlorination facilities increases as the size of community increases. Percentage data for 1945 and 1957 are shown in table 29. In group 1, only 18.1 percent of the plants have chlorination, while in group 8 almost 55 percent of the plants provide chlorination.

### *Grit Removal*

The removal of grit from sewage is practiced at 1,581 treatment plants serving almost 52 million persons. While this represents only 21.0 percent of the treatment plants, they serve almost 68 percent of the population connected to treatment. Percentage increases from 1945 to 1957 were 106.7 and 86.1 percent for treatment plants so equipped and population served, respectively.

Comparative percentage data for 1945 and 1957 are shown in table 29 for the various population groups. Rather striking changes have occurred since 1945 in the plants serving communities of over 1,000 population. The percent of total plants having grit removal devices in these groups has increased substantially.

### *Grease Removal*

Grease removal as an integral unit in the treatment process is reported to be in use at 101 plants in the United States, serving 6.7 million persons. This report indicates fewer persons served in 1957 than in 1945. It is considered that this item may be substantially underreported due to a confusion in the use of coding symbols in the inventory.

### *Acknowledgement*

The data on which the inventory is based were furnished by the various State water pollution control agencies through the Regional Offices of the Public Health Service. Grateful acknowledgment is due the personnel of the State agencies for their cooperation in preparing the base data. In many instances, personnel of the Regional Offices assisted the official agencies, and appreciation is expressed for their very material efforts.

Since this activity has been conducted by the Public Health Service, the data preparation has been performed by Arthur D. Smart. His

valuable and loyal efforts over a period of almost 20 years have been a considerable factor in the success of the inventory.

**NOTE.**—The data presented in this report constitute only a small portion of the material prepared from the inventory. The population group data are a primary classification and were prepared as a single entity. The State data were synthesized from the data by population groups within each State, and the major drainage basin data were synthesized from the individual subbasin data.

These tables are available in the Washington headquarters office of the Public Health Service. Excerpted data will be made available to interested parties. In addition, a variety of special tabulations can be prepared on request.

Any correspondence relating to special tabulations or to the availability of unpublished data should be directed to: Water Supply and Water Pollution Control Program, Public Health Service, U. S. Department of Health, Education, and Welfare, Washington, 25, D. C.
